## GAL20V8

## High Performance E² ${ }^{2}$ MOS PLD <br> Generic Array Logic ${ }^{\text {TM }}$

## FEATURES

- HIGH PERFORMANCE E ${ }^{2}$ CMOS $^{\circledR}$ TECHNOLOGY
- 5 ns Maximum Propagation Delay
- Fmax = 166 MHz
- 4 ns Maximum from Clock Input to Data Output
— UltraMOS ${ }^{\circledR}$ Advanced CMOS Technology
- 50\% to 75\% REDUCTION IN POWER FROM BIPOLAR
- 75mA Typ Icc on Low Power Device
- 45mA Typ Icc on Quarter Power Device
- ACTIVE PULL-UPS ON ALL PINS
- E² CELL TECHNOLOGY
- Reconfigurable Logic
- Reprogrammable Cells
- 100\% Tested/Guaranteed 100\% Yields
- High Speed Electrical Erasure (<100ms)
- 20 Year Data Retention
- EIGHT OUTPUT LOGIC MACROCELLS
- Maximum Flexibility for Complex Logic Designs
- Programmable Output Polarity
- Also Emulates 24-pin PAL ${ }^{\circledR}$ Devices with Full Function/Fuse Map/Parametric Compatibility
- PRELOAD AND POWER-ON RESET OF ALL REGISTERS — 100\% Functional Testability
- APPLICATIONS INCLUDE:
- DMA Control
- State Machine Control
- High Speed Graphics Processing
- Standard Logic Speed Upgrade

## - ELECTRONIC SIGNATURE FOR IDENTIFICATION

## DESCRIPTION

The GAL20V8C, at 5ns maximum propagation delay time, combines a high performance CMOS process with Electrically Erasable $\left(\mathrm{E}^{2}\right)$ floating gate technology to provide the highest speed performance available in the PLD market. High speed erase times ( $<100 \mathrm{~ms}$ ) allow the devices to be reprogrammed quickly and efficiently.
The generic architecture provides maximum design flexibility by allowing the Output Logic Macrocell (OLMC) to be configured by the user. An important subset of the many architecture configurations possible with the GAL20V8 are the PAL architectures listed in the table of the macrocell descriptionsection. GAL20V8 devices are capable of emulating any of these PAL architectures with full function/fuse map/parametric compatibility.
Unique test circuitry and reprogrammable cells allow complete AC, DC, and functional testing during manufacture. As a result, Lattice Semiconductor guarantees $100 \%$ field programmability and functionality of all GAL products. In addition, 100 erase/write cycles and data retention in excess of 20 years are guaranteed.

## PART NUMBER DESCRIPTION

## OUTPUT LOGIC MACROCELL (OLMC)

The following discussion pertains to configuring the output logic macrocell. It should be noted that actual implementation is accomplished by development software/hardware and is completely transparent to the user.

There are three global OLMC configuration modes possible: simple, complex, and registered. Details of each of these modes is illustratedin the following pages. Two global bits, SYN and ACO, control the mode configuration for all macrocells. The XOR bit of each macrocell controls the polarity of the output in any of the three modes, while the AC1 bit of each of the macrocells controls the input/output configuration. These two global and 16 individual architecture bits define all possible configurations in a GAL20V8. The information given on these architecture bits is only to give a better understanding of the device. Compiler software will transparently set these architecture bits from the pin definitions, so the user should not need to directly manipulate these architecture bits.

The following is a list of the PAL architectures that the GAL20V8 can emulate. It also shows the OLMC mode under which the devices emulate the PAL architecture.

| PAL Architectures Emulated by GAL20V8 | GAL20V8 <br> Global OLMC Mode |
| :---: | :---: |
| 20R8 | Registered |
| 20R6 | Registered |
| 20R4 | Registered |
| 20RP8 | Registered |
| 20RP6 | Registered |
| 20RP4 | Registered |
| 20 L 8 | Complex |
| 20H8 | Complex |
| 20P8 | Complex |
| 14L8 | Simple |
| 16L6 | Simple |
| 18L4 | Simple |
| $20 \mathrm{L2}$ | Simple |
| 14H8 | Simple |
| $16 \mathrm{H6}$ | Simple |
| ${ }^{18} \mathrm{H} 4$ | Simple |
| 20 H 2 | Simple |
| $14 \mathrm{P8} 8$ | Simple |
| 16P6 18P4 | Simple Simple |
| 20P2 | Simple |

## COMPILER SUPPORT FOR OLMC

Software compilers support the three different global OLMC modes as different device types. These device types are listed in the table below. Most compilers have the ability to automatically select the device type, generally based on the register usage and output enable (OE) usage. Register usage on the device forces the software to choose the registeredmode. All combinatorial outputs with OE controlledby the productterm will force the software to choose the complex mode. The software will choose the simple mode only when all outputs are dedicated combinatorial without OE control. The different device types listed in the table can be used to override the automatic device selection by the software. For further details, refer to the compiler software manuals.

In registered modepin 1 and pin 13 (DIP pinout) are permanently configured as clock and output enable, respectively. These pins cannot be configuredas dedicatedinputs in the registeredmode.

In complex mode pin 1 and pin 13 becomededicatedinputs and use the feedback paths of pin 22 and pin 15 respectively. Because of this feedback path usage, pin 22 and pin 15 do not have the feedback option in this mode.

In simple mode all feedback paths of the output pins are routed via the adjacent pins. In doing so, the two inner most pins ( pins 18 and 19) will not have the feedback option as these pins are always configured as dedicated combinatorial output.

When using compiler software to configure the device, the user must pay special attention to the following restrictions in each mode.

|  | Registered | Complex | Simple | Auto Mode Select |
| :--- | :---: | :---: | :---: | :---: |

[^1]
## Specifications GAL2OV8

## REGISTERED MODE

In the Registered mode, macrocells are configured as dedicated registered outputs or as I/O functions.

Architecture configurations available in this mode are similar to the common20R8 and 20RP4 devices with various permutations of polarity, I/O and register placement.

All registeredmacrocellsshare common clock and output enable control pins. Any macrocell can be configured as registered or I/O. Up to eight registers or up to eight I/Os are possible in this
mode. Dedicated input or output functions can be implemented as subsets of the I/O function.

Registered outputs have eight product terms per output. I/Os have seven product terms per output.

The JEDEC fuse numbers, including the User Electronic Signature (UES) fuses and the Product Term Disable (PTD) fuses, are shown on the logic diagram on the following page.

Note: The development software configures all of the architecture control bits and checks for proper pin usage automatically.

REGISTERED MODE LOGIC DIAGRAM
DIP (PLCC) Package Pinouts

## Specifications GAL20V8

## COMPLEX MODE

In the Complex mode, macrocells are configured as output only or I/O functions.

Architecture configurations available in this mode are similar to the common20L8 and 20P8 devices with programmablepolarity in each macrocell.

Up to six I/Os are possible in this mode. Dedicated inputs or outputs can be implemented as subsets of the I/O function. The two outer most macrocells (pins 15 \& 22) do not have input ca-
pability. Designs requiring eight $\mathrm{I} / \mathrm{Os}$ can be implemented in the Registered mode.

All macrocells have seven product terms per output. One product term is used for programmableoutput enable control. Pins 1 and 13 are always available as data inputs into the AND array.

The JEDEC fuse numbers including the UES fuses and PTD fuses are shown on the logic diagram on the following page.

Note: The development software configures all of the architecture control bits and checks for proper pin usage automatically.

64-USER ELECTRONIC SIGNATURE FUSES

SYN-2704
AC0-2705

## Specifications GAL20V8

## SIMPLE MODE

In the Simple mode, pins are configured as dedicated inputs or as dedicated, always active, combinatorial outputs.

Architecture configurations available in this mode are similar to the common 14L8 and 16P6 devices with many permutations of generic output polarity or input choices.

Pins 1 and 13 are always available as data inputs into the AND array. The "center" two macrocells(pins 18 \& 19) cannotbe used in the input configuration.

The JEDEC fuse numbers including the UES fuses and PTD fuses are shown on the logic diagram on the following page.

All outputs in the simple mode have a maximum of eight product terms that can control the logic. In addition, each output has programmable polarity.

Note: The development software configures all of the architecture control bits and checks for proper pin usage automatically.

Registered Output

$\overline{\mathrm{OE}}$ to Output Enable/Disable

fmax with Feedback

Specifications GAL20V8

## fmax DESCRIPTIONS

fmax with External Feedback $\mathbf{1 / ( t s u}+\mathbf{t c o}$ )
Note: fmax with external feedback is calculated from measured tsu and tco.

fmax with No Feedback
Note:fmax with no feedback may be less than $1 /(\mathrm{twh}+\mathrm{twl})$. This is to allow for a clock duty cycle of other than $50 \%$.

fmax with Internal Feedback 1/(tsu+tcf)
Note: tcf is a calculated value, derived by subtracting tsu from the period of fmax w/internal feedback (tcf $=1 / \mathrm{fmax}-\mathrm{tsu}$ ). The value of tcf is used primarily when calculating the delay from clocking a register to a combinatorial output (through registered feedback), as shown above. For example, the timing from clock to a combinatorial output is equal to $\mathbf{t c f}+$ tpd.

## SWITCHING TEST CONDITIONS

| Input Pulse Levels |  | GND to 3.0V |
| :--- | :---: | :---: |
| Input Rise and | GAL20V8B | $2-3 \mathrm{~ns} \mathrm{10} \mathrm{\%-90} \mathrm{\%}$ |
| Fall Times | GAL20V8C | $1.5 \mathrm{~ns} \mathrm{10} \mathrm{\%-90} \mathrm{\%}$ |
| Input Timing Reference Levels | 1.5 V |  |
| Output Timing Reference Levels | 1.5 V |  |
| Output Load |  | See Figure |

3 -state levels are measured 0.5 V from steady-state active
level.

## GAL20V8B Output Load Conditions (see figure)

| Test Condition |  | $\mathbf{R}_{\mathbf{1}}$ | $\mathbf{R}_{\mathbf{2}}$ | $\mathbf{C L}$ |
| :---: | :--- | :---: | :---: | :---: |
| A |  | $200 \Omega$ | $390 \Omega$ | 50 pF |
| B | Active High | $\infty$ | $390 \Omega$ | 50 pF |
|  | Active Low | $200 \Omega$ | $390 \Omega$ | 50 pF |
| C | Active High | $\infty$ | $390 \Omega$ | 5 pF |
|  | Active Low | $200 \Omega$ | $390 \Omega$ | 5 pF |

${ }^{*} C_{L}$ INCLUDES TEST FIXTURE AND PROBE CAPACITANCE

## GAL20V8C Output Load Conditions (see figure)

| Test Condition |  | $\mathbf{R}_{1}$ | $\mathbf{R}_{\mathbf{2}}$ | $\mathbf{C L}$ |
| :---: | :--- | :---: | :---: | :---: |
| A |  | $200 \Omega$ | $200 \Omega$ | 50 pF |
| B | Active High | $\infty$ | $200 \Omega$ | 50 pF |
|  | Active Low | $200 \Omega$ | $200 \Omega$ | 50 pF |
| C | Active High | $\infty$ | $200 \Omega$ | 5 pF |
|  | Active Low | $200 \Omega$ | $200 \Omega$ | 5 pF |

## Specifications GAL20V8

## ELECTRONIC SIGNATURE

An electronic signature is provided in every GAL20V8 device. It contains 64 bits of reprogrammable memory that can contain user defined data. Some uses include user ID codes, revision numbers, or inventory control. The signature data is always available to the user independent of the state of the security cell.

NOTE: The electronic signature is included in checksum calculations. Changing the electronic signature will alter the checksum.

## SECURITY CELL

A security cell is providedin the GAL20V8 devices to preventunauthorized copying of the array patterns. Once programmed,this cell prevents further read access to the functional bits in the device. This cell can only be erased by re-programmingthe device, so the original configuration can never be examinedonce this cell is programmed. The Electronic Signature is always available to the user, regardless of the state of this control cell.

## LATCH-UP PROTECTION

GAL20V8 devices are designed with an on-board charge pump to negativelybias the substrate. The negative bias minimizes the potential of latch-up caused by negative input undershoots. Additionally, outputs are designed with n -channel pull-ups instead of the traditional p-channel pull-ups in order to eliminate latch-up due to output overshoots.

## DEVICE PROGRAMMING

GAL devices are programmed using a Lattice Semiconductorapproved Logic Programmer, available from a number of manufacturers. Complete programming of the device takes only a few seconds. Erasing of the device is transparent to the user, and is done automatically as part of the programming cycle.

## OUTPUT REGISTER PRELOAD

When testing state machine designs, all possible states and state transitions must be verified in the design, not just those required in the normal machine operations. This is because, in system operation, certain events occur that may throw the logic into an illegal state (power-up,line voltage glitches, brown-outs,etc.). To test a design for proper treatment of these conditions, a way must be provided to break the feedback paths, and force any desired (i.e., illegal) state into the registers. Then the machine can be sequenced and the outputs tested for correct next state conditions.

GAL20V8 devices include circuitry that allows each registered output to be synchronously set either high or low. Thus, any present state condition can be forced for test sequencing. If necessary, approved GAL programmers capable of executing text vectors perform output register preload automatically.

## INPUT BUFFERS

GAL20V8 devices are designed with TTL level compatible input buffers. These buffers have a characteristicallyhigh impedance, and present a much lighter load to the driving logic than bipolar TTL devices.

The GAL20V8 input and I/O pins have built-in active pull-ups. As a result, unused inputs and I/O's will float to a TTL "high" (logical "1"). Lattice Semiconductor recommends that all unused inputs and tri-stated I/O pins be connected to another active input, VCC, or Ground. Doing this will tend to improve noise immunity and reduce Icc for the device.

Typical Input Pull-up Characteristic

POWER-UP RESET

Circuitry within the GAL20V8 provides a reset signal to all registers during power-up. All internal registers will have their Q outputs set low after a specified time (tpr, $1 \mu \mathrm{~s} \mathrm{MAX}$ ). As a result, the state on the registered output pins (if they are enabled) will always be high on power-up, regardless of the programmed polarity of the output pins. This feature can greatly simplify state machine design by providing a known state on power-up. Because of the asynchronous nature of system power-up, some
conditions must be met to guarantee a valid power-up reset of the device. First, the Vcc rise must be monotonic. Second, the clock input must be at static TTL level as shown in the diagram during power up. The registers will reset within a maximum of tpr time. As in normal system operation, avoid clocking the device until all input and feedback path setup times have been met. The clock must also meet the minimum pulse width requirements.
